

COMS W4156 Advanced Software Engineering (ASE)

November 7, 2024

On this day ...

Agenda

1. From CRC Cards to Code
2. Design Principles
3. Reminders

How to get from CRC Cards to Code

First check whether any CRC “classes” can be implemented by already available components, including libraries and services. This might require [adapters](#)

Then other CRC classes will typically be implemented by a newly written class, module, file, etc. - the programming language’s modular unit

The responsibilities correspond to the modular unit’s methods, functions, procedures, subroutines, etc., with access to the collaborators via parameters, object or class fields, global variables, shared data structures, etc.

Note updating fields, global variables, shared data structures = “side-effects”

Turn over your CRC card

Class Name: Customer

- Customer ID (int)
- First Name (string)
- Last Name (string)
- Email Address (string)
- Phone Number (string)
- Billing Address (Address object)
- Purchase History (List of Order objects)
- Loyalty Points (int)

Address and Order are collaborators

On the back, list:

Class or other component name (not necessarily same as on front, e.g., if reusing existing software)

Object fields maintained by instances of the class - local data as well as references to collaborators

Any class fields maintained by the class itself

Sometimes also methods that carry out the responsibilities - signature with name, parameter list, return types, side-effects

More on Side-Effects

Avoid when possible

But if your units must have side-effects, then unit testing needs to consider inputs and outputs from/to shared state

Mock shared state outside the class during unit testing, then replace with real resources during integration. Mocks must "remember" changes to shared state that will be read after written

```
int foo (Obj o, int x) {  
    ...  
    o.ffield = o.anotherfield / x;  
    ...  
    do something with o.ffield;  
    ....  
    return something;  
}
```

Consider foo in class that defines Obj

Consider foo in another class than Obj

Debugging CRC Cards, Revisited

Again, animate the use cases - move the cards around on a table or board

- to make sure:

- every trigger is accounted for,
- every precondition is checked,
- every postcondition indeed becomes true, and
- every step in each basic, alternative and exception flows is accounted for

The First CRC Cards

Remember there is no Global Master

When “the system” or “the software” does something, that means some class in the system does it

There should not be any global class that does everything and/or is related to everything else

Give up global knowledge of control and rely on local knowledge of objects to accomplish their tasks

Agenda

1. From CRC Cards to Code
2. Design Principles
3. Reminders

Keep Design Principles In Mind

For each extended CRC card (extended by the details on the back), consider design principles applicable to that component and/or its collaborations with other components

Design Principle = general technique to avoid bad design (or, phrased positively, create good designs)

Bad design is:

- Rigid - Hard to change the code because every change affects too many other parts of the system.
- Fragile - When you make a change to some part of the code, unexpected parts of the system break.
- Immobile - Hard to reuse some of the code in another system because it cannot be disentangled from the current system.

You Aren't Gonna Need It ([YAGNI](#)): do the simplest design that could possibly work for the functionality needed NOW (this iteration)

“SOLID” Software Engineering Design Principles

1. **S**ingle Responsibility
2. **O**pen/Closed
3. **L**iskov Substitution
4. **I**nterface Segregation
5. **D**ependency Inversion

Design Principle != Design Pattern

(design patterns next week)

Single Responsibility Principle (SRP)

Every module (or class) should have a single responsibility, and all its methods should contribute to fulfilling that responsibility - move any methods that don't belong to another component

Seemingly contradicts the multiple “responsibilities” of CRC cards, which refer to finer granularity tasks that should all be part of the same focused single purpose. Perhaps better to call it the Single Purpose Principle (SPP)

- ❑ problem: If a class has multiple purposes, then it is more likely to be affected by a requirements change: It knows too much
- ❑ solution: Break up the functionality into multiple classes, where each individual class has only one purpose. Leads to more smaller classes

Greater cohesion, lower coupling, fewer test cases

SRP

Sanity check 1: Can you describe the component's purpose in one sentence without using the word “and”?

Sanity check 2: Does it make sense to say “The <class name> <method name> itself” for each method? (after fixing grammar)

Sanity check 3: Does the component know/do too much?
Recall [code smell “bloaters”](#)

[SRP Example](#)

What are Cohesion and Coupling?

Maximize *Cohesion* = degree to which program unit exhibits a single purpose.
Addressed by Single Responsibility Principle

Minimize *Coupling* = interdependencies among program units, “need to know”.
The degree to which one component C depends on the “innards” of another component D, as opposed to its interface, so that if component D changes internally then component C also needs to change. Addressed by the other SOLID principles. Recall code smell "couplers"

Open-Closed Principle (OCP)

Code units should be “open for extension and closed for modification”, to allow change without modifying any existing code that works because change introduces new bugs (“[regression](#)”)

Seemingly contradicts refactoring, but most [refactoring operations](#) (discussed next week) seek to move out parts of the code to leave behind an OCP code unit

OCP

Backwards compatibility

Since requirements change, we need to be able to change existing program behavior

- Change the behavior of an existing class by deriving a new subclass ([inheritance](#))
- Change the behavior of an existing class by composition with a new class ([delegation](#))
- Change the behavior of an existing method by adding a wrapper ([adapter](#)) around that function
- Change the behavior of a library or service by adding new API functions or a new implementation of the same [interface](#)

Once upon a time, the conventional way to change the behavior of an existing class was to derive a new subclass, i.e., inheritance, but alternatives are often better

Notice CRC cards have composition (collaborators) but no inheritance - you can still implement using inheritance (in an OO programming language), but be careful about violating LSP and ISP principles!

Liskov Substitution Principle (LSP)

Extends the inheritance variant of OCP to require that subtypes must be substitutable for their base types ([polymorphism](#))

If class *A* is a subtype of class *B*, then we should be able to replace *B* with *A* without disrupting the behavior of our program

If it looks like a duck and quacks like a duck but it needs batteries, you probably have the wrong abstraction.

LSP

Do inherited methods make sense for instances of the derived class? Do overridden methods take the same parameter types and return the same types as the base class? Do they have side-effects on the same data?

If not, then we are not actually inheriting - instead should delegate any common functionality, and if there is no common functionality then there's no relationship at all so why pretend?

Code already using references to the base classes should be able to use instances of the derived classes without being aware of the switch

Design by Contract

The contract of a method informs the author of a class about the behaviors that they can safely rely on

The contract could be specified by declaring preconditions and postconditions for each method: The preconditions must be true in order for the method to execute. On completion, after executing the method, the method guarantees that the postconditions are true

Derived classes need to fulfill the same contract

Interface Segregation Principle (ISP)

CRC cards can be thought of as modeling [interfaces](#) instead of how those interfaces are implemented in code

Components that implement an interface should only have to provide implementations of the methods relevant to them

Clients should not be forced to depend upon interfaces they do not use

Large interfaces should be split into smaller ones

Interface Segregation Principle

If IRequireFood, I want to Eat(Food food) not,
LightCandelabra() or LayoutCutlery(CutleryLayout preferredLayout)

ISP

Analogous to SRP: If an interface has multiple purposes, then it is more likely to be affected by a requirements change

Break up into multiple interfaces, where each individual interface has only one purpose. Leads to more smaller interfaces

Dependency Inversion Principle (DIP)

High-level modules should not depend on low-level modules, which makes it hard to reuse the high-level modules

Both should depend on abstractions

Abstractions should not depend on details - details should depend on abstractions

DIP

DIP does not just change the *direction* of the dependency, it *splits* the dependency between the high-level and low-level modules by introducing an abstraction between them

This seemingly contradicts the [layered architectural style](#), where each layer builds on the layer below - the contradiction is resolved by depending on an abstraction of the layer below, not the details of the lower layer

“SOLID” Software Engineering Design Principles

1. **Single Responsibility**
2. **Open/Closed**
3. **Liskov Substitution**
4. **Interface Segregation**
5. **Dependency Inversion**

Single Responsibility Principle

A class should have only a single responsibility (i.e. only one potential change in the software's specification should be able to affect the specification of the class)

Open / Closed Principle

A software module (it can be a class or method) should be open for extension but closed for modification.

Liskov Substitution Principle

Objects in a program should be replaceable with instances of their subtypes without altering the correctness of that program.

Interface Segregation Principle

Clients should not be forced to depend upon the interfaces that they do not use.

Dependency Inversion Principle

Program to an interface, not to an implementation.

Don't Repeat Yourself principle (DRY)

Another D - SOLIDD?

Avoid duplicate code and redundant work, instead abstract out common code and put in a single location

Make sure that you only implement each feature and requirement once

DRY is about putting a piece of functionality in one place vs. SRP is about making sure a class does only one thing

DRY

Sanity check: During CRC animation, are there two or more ways to fulfill the same use case or flow?

But don't go too far...

“ARID” = All Readability is Dead

Types of Clones

Original code

```
int main() {  
    int x = 1;  
    int y = x + 5;  
    return y;  
}
```

```
int func1() {  
    int x = 1;  
    int y = x + 5;  
    return y;  
}
```

Exact match

```
int func2() {  
    int p = 1;  
    int q = p + 5;  
    return q;  
}
```

Exact match, with
only the variable
names differing

```
int func3() {  
    int s = 1;  
    int t = s + 5;  
    s++;  
    return t;  
}
```

Near exact match

As defined in an experiment comparing existing clone detection techniques at the 1st International Workshop on Detection of Software Clones (02)

Agenda

1. From CRC Cards to Code
2. Design Principles
3. Reminders

Rest of Semester Milestones

Second Iteration due November 25
(Monday before Thanksgiving)

Second Iteration Demo due December 6
(Friday the week after Thanksgiving)

Second Assessment Friday December 6
12:01AM to Monday December 9
11:59PM (last day of classes and the day
before university "study days")

Demo Day Monday December 16 10AM to
4PM (Monday of finals week)

Next Week

Refactoring

(Some) Design Patterns

Ask Me Anything
